Regularization

Welcome to the second assignment of this week. Deep Learning models have so much flexibility and capacity that **overfitting can be a serious problem**, if the training dataset is not big enough. Sure it does well on the training set, but the learned network **doesn't generalize to new examples** that it has never seen!

You will learn to: Use regularization in your deep learning models.

Let's first import the packages you are going to use.

```
In [1]:  # import packages
         import numpy as np
         import matplotlib.pyplot as plt
         from reg_utils import sigmoid, relu, plot_decision_boundary, initialize_parame
         ters, load_2D_dataset, predict_dec
         from reg_utils import compute_cost, predict, forward_propagation, backward_pro
         pagation, update_parameters
         import sklearn
         import sklearn.datasets
         import scipy.io
         from testCases import *

         %matplotlib inline
         plt.rcParams['figure.figsize'] = (7.0, 4.0) # set default size of plots
         plt.rcParams['image.interpolation'] = 'nearest'
         plt.rcParams['image.cmap'] = 'gray'
```

Problem Statement: You have just been hired as an AI expert by the French Football Corporation. They would like you to recommend positions where France's goal keeper should kick the ball so that the French team's players can then hit it with their head.

Figure 1 : **Football field**

The goal keeper kicks the ball in the air, the players of each team are fighting to hit the ball with their head

They give you the following 2D dataset from France's past 10 games.

```
In [2]:   train_X, train_Y, test_X, test_Y = load_2D_dataset()
```

Each dot corresponds to a position on the football field where a football player has hit the ball with his/her head after the French goal keeper has shot the ball from the left side of the football field.

- If the dot is blue, it means the French player managed to hit the ball with his/her head
- If the dot is red, it means the other team's player hit the ball with their head

Your goal: Use a deep learning model to find the positions on the field where the goalkeeper should kick the ball.

Analysis of the dataset: This dataset is a little noisy, but it looks like a diagonal line separating the upper left half (blue) from the lower right half (red) would work well.

You will first try a non-regularized model. Then you'll learn how to regularize it and decide which model you will choose to solve the French Football Corporation's problem.

1 - Non-regularized model

You will use the following neural network (already implemented for you below). This model can be used:

- in *regularization mode* -- by setting the `lambd` input to a non-zero value. We use "`lambd`" instead of "`lambda`" because "`lambda`" is a reserved keyword in Python.
- in *dropout mode* -- by setting the `keep_prob` to a value less than one

You will first try the model without any regularization. Then, you will implement:

- *L2 regularization* -- functions: "`compute_cost_with_regularization()`" and "`backward_propagation_with_regularization()`"
- *Dropout* -- functions: "`forward_propagation_with_dropout()`" and "`backward_propagation_with_dropout()`"

In each part, you will run this model with the correct inputs so that it calls the functions you've implemented. Take a look at the code below to familiarize yourself with the model.

```
In [3]: def model(X, Y, learning_rate = 0.3, num_iterations = 30000, print_cost = T
        rue, lambd = 0, keep_prob = 1):
            """
            Implements a three-layer neural network: LINEAR->RELU->LINEAR->RELU->LI
        NEAR->SIGMOID.

            Arguments:
            X -- input data, of shape (input size, number of examples)
            Y -- true "label" vector (1 for blue dot / 0 for red dot), of shape (ou
        tput size, number of examples)
            learning_rate -- learning rate of the optimization
            num_iterations -- number of iterations of the optimization loop
            print_cost -- If True, print the cost every 10000 iterations
            lambd -- regularization hyperparameter, scalar
            keep_prob - probability of keeping a neuron active during drop-out, sca
        lar.

            Returns:
            parameters -- parameters learned by the model. They can then be used to
         predict.
            """

            grads = {}
            costs = []                          # to keep track of the cost
            m = X.shape[1]                      # number of examples
            layers_dims = [X.shape[0], 20, 3, 1]

            # Initialize parameters dictionary.
            parameters = initialize_parameters(layers_dims)

            # Loop (gradient descent)
```

```python
    for i in range(0, num_iterations):

        # Forward propagation: LINEAR -> RELU -> LINEAR -> RELU -> LINEAR -> SIGMOID.
        if keep_prob == 1:
            a3, cache = forward_propagation(X, parameters)
        elif keep_prob < 1:
            a3, cache = forward_propagation_with_dropout(X, parameters, keep_prob)

        # Cost function
        if lambd == 0:
            cost = compute_cost(a3, Y)
        else:
            cost = compute_cost_with_regularization(a3, Y, parameters, lambd)

        # Backward propagation.
        assert(lambd==0 or keep_prob==1)     # it is possible to use both L2 regularization and dropout,
                                             # but this assignment will only explore one at a time
        if lambd == 0 and keep_prob == 1:
            grads = backward_propagation(X, Y, cache)
        elif lambd != 0:
            grads = backward_propagation_with_regularization(X, Y, cache, lambd)
        elif keep_prob < 1:
            grads = backward_propagation_with_dropout(X, Y, cache, keep_prob)

        # Update parameters.
        parameters = update_parameters(parameters, grads, learning_rate)

        # Print the loss every 10000 iterations
        if print_cost and i % 10000 == 0:
            print("Cost after iteration {}: {}".format(i, cost))
        if print_cost and i % 1000 == 0:
            costs.append(cost)

    # plot the cost
    plt.plot(costs)
    plt.ylabel('cost')
    plt.xlabel('iterations (x1,000)')
    plt.title("Learning rate =" + str(learning_rate))
    plt.show()

    return parameters
```

Let's train the model without any regularization, and observe the accuracy on the train/test sets.

```
In [4]:  parameters = model(train_X, train_Y)
         print ("On the training set:")
         predictions_train = predict(train_X, train_Y, parameters)
         print ("On the test set:")
         predictions_test = predict(test_X, test_Y, parameters)
```

Cost after iteration 0: 0.6557412523481002
Cost after iteration 10000: 0.16329987525724216
Cost after iteration 20000: 0.13851642423255986

Learning rate =0.3
On the training set:
Accuracy: 0.947867298578
On the test set:
Accuracy: 0.915

The train accuracy is 94.8% while the test accuracy is 91.5%. This is the **baseline model** (you will observe the impact of regularization on this model). Run the following code to plot the decision boundary of your model.

```
In [5]: plt.title("Model without regularization")
        axes = plt.gca()
        axes.set_xlim([-0.75,0.40])
        axes.set_ylim([-0.75,0.65])
        plot_decision_boundary(lambda x: predict_dec(parameters, x.T), train_X, train_
        Y)
```

Model without regularization
The non-regularized model is obviously overfitting the training set. It is fitting the noisy points! Lets now look at two techniques to reduce overfitting.

2 - L2 Regularization

The standard way to avoid overfitting is called **L2 regularization**. It consists of appropriately modifying your cost function, from:

$$J = -\frac{1}{m} \sum_{i=1}^{m} \left(y^{(i)} \log\left(a^{[L](i)} \right) + (1 - y^{(i)}) \log\left(1 - a^{[L](i)} \right) \right)$$

To:

$$J_{regularized} = \underbrace{-\frac{1}{m} \sum_{i=1}^{m} \left(y^{(i)} \log\left(a^{[L](i)} \right) + (1 - y^{(i)}) \log\left(1 - a^{[L](i)} \right) \right)}_{\text{cross-entropy cost}} + \underbrace{\frac{1}{m} \frac{\lambda}{2} \sum_{l} \sum_{k} \sum_{j} W_{k,j}^{[l]2}}_{\text{L2 regularization cost}}$$

Let's modify your cost and observe the consequences.

Exercise: Implement `compute_cost_with_regularization()` which computes the cost given by formula (2). To calculate $\sum_{k} \sum_{j} W_{k,j}^{[l]2}$, use :

    np.sum(np.square(Wl))

Note that you have to do this for $W^{[1]}$, $W^{[2]}$ and $W^{[3]}$, then sum the three terms and multiply by $\frac{1}{m} \frac{\lambda}{2}$.

```
# GRADED FUNCTION: compute_cost_with_regularization

def compute_cost_with_regularization(A3, Y, parameters, lambd):
    """
    Implement the cost function with L2 regularization. See formula (2) above.

    Arguments:
    A3 -- post-activation, output of forward propagation, of shape (output siz
e, number of examples)
    Y -- "true" labels vector, of shape (output size, number of examples)
    parameters -- python dictionary containing parameters of the model

    Returns:
    cost - value of the regularized loss function (formula (2))
    """
    m = Y.shape[1]
    W1 = parameters["W1"]
    W2 = parameters["W2"]
    W3 = parameters["W3"]

    cross_entropy_cost = compute_cost(A3, Y) # This gives you the cross-entrop
y part of the cost

    ### START CODE HERE ### (approx. 1 line)
    L2_regularization_cost = lambd/2*1/m*(np.sum(np.square(W1))+np.sum(np.squa
re(W2))+np.sum(np.square(W3)))
    ### END CODER HERE ###

    cost = cross_entropy_cost + L2_regularization_cost

    return cost
```

In [8]:
```
A3, Y_assess, parameters = compute_cost_with_regularization_test_case()

print("cost = " + str(compute_cost_with_regularization(A3, Y_assess, parameter
s, lambd = 0.1)))
```

```
cost = 1.78648594516
```

Expected Output:

cost	1.78648594516

Of course, because you changed the cost, you have to change backward propagation as well! All the gradients have to be computed with respect to this new cost.

Exercise: Implement the changes needed in backward propagation to take into account regularization. The changes only concern dW1, dW2 and dW3. For each, you have to add the regularization term's gradient ($\frac{d}{dW}(\frac{1}{2}\frac{\lambda}{m}W^2) = \frac{\lambda}{m}W$).

```python
In [9]:  # GRADED FUNCTION: backward_propagation_with_regularization

         def backward_propagation_with_regularization(X, Y, cache, lambd):
             """
             Implements the backward propagation of our baseline model to which we a
         dded an L2 regularization.

             Arguments:
             X -- input dataset, of shape (input size, number of examples)
             Y -- "true" labels vector, of shape (output size, number of examples)
             cache -- cache output from forward_propagation()
             lambd -- regularization hyperparameter, scalar

             Returns:
             gradients -- A dictionary with the gradients with respect to each param
         eter, activation and pre-activation variables
             """

             m = X.shape[1]
             (Z1, A1, W1, b1, Z2, A2, W2, b2, Z3, A3, W3, b3) = cache

             dZ3 = A3 - Y

             ### START CODE HERE ### (approx. 1 line)
             dW3 = 1./m * np.dot(dZ3, A2.T) +  lambd/m*W3
             ### END CODE HERE ###
             db3 = 1./m * np.sum(dZ3, axis=1, keepdims = True)

             dA2 = np.dot(W3.T, dZ3)
             dZ2 = np.multiply(dA2, np.int64(A2 > 0))
             ### START CODE HERE ### (approx. 1 line)
             dW2 = 1./m * np.dot(dZ2, A1.T) +  lambd/m*W2
             ### END CODE HERE ###
             db2 = 1./m * np.sum(dZ2, axis=1, keepdims = True)

                          "dZ2": dZ2, "dW2": dW2, "db2": db2, "dA1": dA1,
                          "dZ1": dZ1, "dW1": dW1, "db1": db1}

             return gradients
```

```
In [10]: X_assess, Y_assess, cache = backward_propagation_with_regularization_test_case
         ()

         grads = backward_propagation_with_regularization(X_assess, Y_assess, cache, la
         mbd = 0.7)
         print ("dW1 = "+ str(grads["dW1"]))
         print ("dW2 = "+ str(grads["dW2"]))
         print ("dW3 = "+ str(grads["dW3"]))
```

```
dW1 = [[-0.25604646  0.12298827 -0.28297129]
 [-0.17706303  0.34536094 -0.4410571 ]]
dW2 = [[ 0.79276486  0.85133918]
 [-0.0957219  -0.01720463]
 [-0.13100772 -0.03750433]]
dW3 = [[-1.77691347 -0.11832879 -0.09397446]]
```

Expected Output:

dW1	[[-0.25604646 0.12298827 -0.28297129] [-0.17706303 0.34536094 -0.4410571]]
dW2	[[0.79276486 0.85133918] [-0.0957219 -0.01720463] [-0.13100772 -0.03750433]]
dW3	[[-1.77691347 -0.11832879 -0.09397446]]

Let's now run the model with L2 regularization ($\lambda = 0.7$). The model() function will call:

- compute_cost_with_regularization instead of compute_cost
- backward_propagation_with_regularization instead of backward_propagation

```
In [11]: parameters = model(train_X, train_Y, lambd = 0.7)
         print ("On the train set:")
         predictions_train = predict(train_X, train_Y, parameters)
         print ("On the test set:")
         predictions_test = predict(test_X, test_Y, parameters)
```

Cost after iteration 0: 0.6974484493131264
Cost after iteration 10000: 0.2684918873282239
Cost after iteration 20000: 0.2680916337127301
On the train set:
Accuracy: 0.938388625592
On the test set:
Accuracy: 0.93

Congrats, the test set accuracy increased to 93%. You have saved the French football team!

You are not overfitting the training data anymore. Let's plot the decision boundary.

```
In [12]:  plt.title("Model with L2-regularization")
          axes = plt.gca()
          axes.set_xlim([-0.75,0.40])
          axes.set_ylim([-0.75,0.65])
          plot_decision_boundary(lambda x: predict_dec(parameters, x.T), train_X, train_
          Y)
```

Model with L2-regularization
Observations:

- The value of λ is a hyperparameter that you can tune using a dev set.
- L2 regularization makes your decision boundary smoother. If λ is too large, it is also possible to "oversmooth", resulting in a model with high bias.

**What is L2-regularization actually doing?**:

L2-regularization relies on the assumption that a model with small weights is simpler than a model with large weights. Thus, by penalizing the square values of the weights in the cost function you drive all the weights to smaller values. It becomes too costly for the cost to have large weights! This leads to a smoother model in which the output changes more slowly as the input changes.

What you should remember -- the implications of L2-regularization on:
- The cost computation:
  - A regularization term is added to the cost
- The backpropagation function:
  - There are extra terms in the gradients with respect to weight matrices
- Weights end up smaller ("weight decay"):
  - Weights are pushed to smaller values.

3 - Dropout

Finally, **dropout** is a widely used regularization technique that is specific to deep learning. **It randomly shuts down some neurons in each iteration.** Watch these two videos to see what this means!
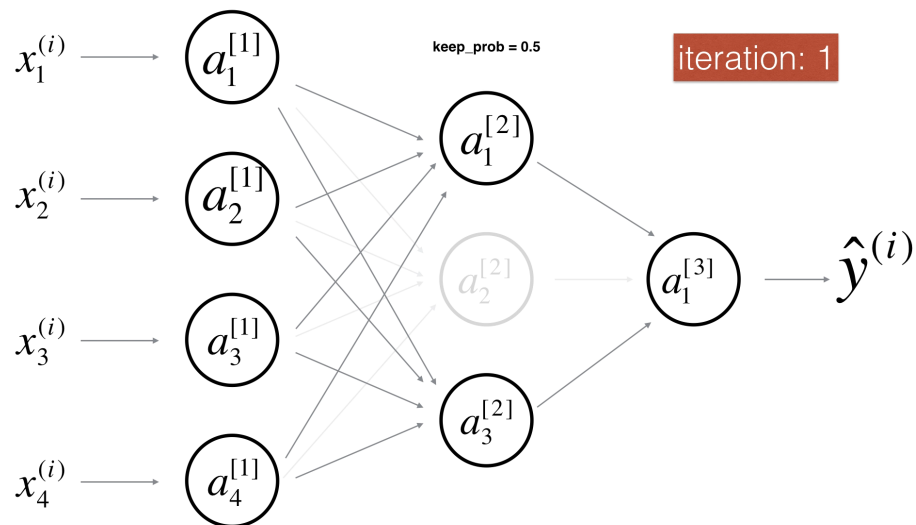

0:00 / 0:08

Figure 2 : Drop-out on the second hidden layer.
At each iteration, you shut down (= set to zero) each neuron of a layer with probability $1 - keep\_prob$ or keep it with probability $keep\_prob$ (50% here). The dropped neurons don't contribute to the training in both the forward and backward propagations of the iteration.

0:00

<u>Figure 3</u> : Drop-out on the first and third hidden layers.
1st layer: we shut down on average 40% of the neurons. 3rd layer: we shut down on average 20% of the neurons.

When you shut some neurons down, you actually modify your model. The idea behind drop-out is that at each iteration, you train a different model that uses only a subset of your neurons. With dropout, your neurons thus become less sensitive to the activation of one other specific neuron, because that other neuron might be shut down at any time.

3.1 - Forward propagation with dropout

Exercise: Implement the forward propagation with dropout. You are using a 3 layer neural network, and will add dropout to the first and second hidden layers. We will not apply dropout to the input layer or output layer.

Instructions: You would like to shut down some neurons in the first and second layers. To do that, you are going to carry out 4 Steps:

1. In lecture, we dicussed creating a variable $d^{[1]}$ with the same shape as $a^{[1]}$ using np.random.rand() to randomly get numbers between 0 and 1. Here, you will use a vectorized implementation, so create a random matrix $D^{[1]} = [d^{[1](1)} d^{[1](2)} \ldots d^{[1](m)}]$ of the same dimension as $A^{[1]}$.
2. Set each entry of $D^{[1]}$ to be 0 with probability (1-keep_prob) or 1 with probability (keep_prob), by thresholding values in $D^{[1]}$ appropriately. Hint: to set all the entries of a matrix X to 0 (if entry is less than 0.5) or 1 (if entry is more than 0.5) you would do: X = (X < 0.5). Note that 0 and 1 are respectively equivalent to False and True.
3. Set $A^{[1]}$ to $A^{[1]} * D^{[1]}$. (You are shutting down some neurons). You can think of $D^{[1]}$ as a mask, so that when it is multiplied with another matrix, it shuts down some of the values.
4. Divide $A^{[1]}$ by keep_prob. By doing this you are assuring that the result of the cost will still have the same expected value as without drop-out. (This technique is also called inverted dropout.)

```
In [22]:   # GRADED FUNCTION: forward_propagation_with_dropout

           def forward_propagation_with_dropout(X, parameters, keep_prob = 0.5):
               """
               Implements the forward propagation: LINEAR -> RELU + DROPOUT -> LINEAR
             -> RELU + DROPOUT -> LINEAR -> SIGMOID.

               Arguments:
               X -- input dataset, of shape (2, number of examples)
               parameters -- python dictionary containing your parameters "W1", "b1",
             "W2", "b2", "W3", "b3":
                               W1 -- weight matrix of shape (20, 2)

3.2 - Backward propagation with dropout

Exercise: Implement the backward propagation with dropout. As before, you are training a 3 layer network. Add dropout to the first and second hidden layers, using the masks $D^{[1]}$ and $D^{[2]}$ stored in the cache.

Instruction: Backpropagation with dropout is actually quite easy. You will have to carry out 2 Steps:

1. You had previously shut down some neurons during forward propagation, by applying a mask $D^{[1]}$ to A1. In backpropagation, you will have to shut down the same neurons, by reapplying the same mask $D^{[1]}$ to dA1.
2. During forward propagation, you had divided A1 by keep_prob. In backpropagation, you'll therefore have to divide dA1 by keep_prob again (the calculus interpretation is that if $A^{[1]}$ is scaled by keep_prob, then its derivative $dA^{[1]}$ is also scaled by the same keep_prob).

```
In [24]:  # GRADED FUNCTION: backward_propagation_with_dropout

          def backward_propagation_with_dropout(X, Y, cache, keep_prob):
              """
              Implements the backward propagation of our baseline model to which we a
          dded dropout.

              Arguments:
              X -- input dataset, of shape (2, number of examples)
              Y -- "true" labels vector, of shape (output size, number of examples)
              cache -- cache output from forward_propagation_with_dropout()
              keep_prob - probability of keeping a neuron active during drop-out, sca
          lar

              Returns:
              gradients -- A dictionary with the gradients with respect to each param
          eter, activation and pre-activation variables
              """

              m = X.shape[1]
              (Z1, D1, A1, W1, b1, Z2, D2, A2, W2, b2, Z3, A3, W3, b3) = cache

Expected Output:

dA1	[[0.36544439 0. -0.00188233 0. -0.17408748] [0.65515713 0. -0.00337459 0. -0.]]
dA2	[[0.58180856 0. -0.00299679 0. -0.27715731] [0. 0.53159854 -0. 0.53159854 -0.34089673] [0. 0. -0.00292733 0. -0.]]

Let's now run the model with dropout (keep_prob = 0.86). It means at every iteration you shut down each neurons of layer 1 and 2 with 14% probability. The function model() will now call:

- forward_propagation_with_dropout instead of forward_propagation.
- backward_propagation_with_dropout instead of backward_propagation.
```
In [26]:  parameters = model(train_X, train_Y, keep_prob = 0.86, learning_rate = 0.3)

          print ("On the train set:")
          predictions_train = predict(train_X, train_Y, parameters)
          print ("On the test set:")
          predictions_test = predict(test_X, test_Y, parameters)
```

Cost after iteration 0: 0.6543912405149825

Cost after iteration 10000: 0.06101698657490559
Cost after iteration 20000: 0.060582435798513114

On the train set:
Accuracy: 0.928909952607
On the test set:
Accuracy: 0.95

Dropout works great! The test accuracy has increased again (to 95%)! Your model is not overfitting the training set and does a great job on the test set. The French football team will be forever grateful to you!

Run the code below to plot the decision boundary.

```
In [27]:  plt.title("Model with dropout")
          axes = plt.gca()
          axes.set_xlim([-0.75,0.40])
          axes.set_ylim([-0.75,0.65])
          plot_decision_boundary(lambda x: predict_dec(parameters, x.T), train_X, train_
          Y)
```

Model with dropout
Note:

- A **common mistake** when using dropout is to use it both in training and testing. You should use dropout (randomly eliminate nodes) only in training.
- Deep learning frameworks like tensorflow (https://www.tensorflow.org/api_docs/python/tf/nn/dropout), PaddlePaddle (http://doc.paddlepaddle.org/release_doc/0.9.0/doc/ui/api/trainer_config_helpers/attrs.html), keras (https://keras.io/layers/core/#dropout) or caffe (http://caffe.berkeleyvision.org/tutorial/layers/dropout.html) come with a dropout layer implementation. Don't stress - you will soon learn some of these frameworks.

What you should remember about dropout:
- Dropout is a regularization technique.
- You only use dropout during training. Don't use dropout (randomly eliminate nodes) during test time.
- Apply dropout both during forward and backward propagation.
- During training time, divide each dropout layer by keep_prob to keep the same expected value for the activations. For example, if keep_prob is 0.5, then we will on average shut down half the nodes, so the output will be scaled by 0.5 since only the remaining half are contributing to the solution. Dividing by 0.5 is equivalent to multiplying by 2. Hence, the output now has the same expected value. You can check that this works even when keep_prob is other values than 0.5.

4 - Conclusions

Here are the results of our three models:

model	**train accuracy**	**test accuracy**
3-layer NN without regularization	95%	91.5%
3-layer NN with L2-regularization	94%	93%
3-layer NN with dropout	93%	95%

Note that regularization hurts training set performance! This is because it limits the ability of the network to overfit to the training set. But since it ultimately gives better test accuracy, it is helping your system.

Congratulations for finishing this assignment! And also for revolutionizing French football. :-)

What we want you to remember from this notebook:
- Regularization will help you reduce overfitting.
- Regularization will drive your weights to lower values.
- L2 regularization and Dropout are two very effective regularization techniques.
